# SCIENTIFIC RESULTS OF EXPLORATIONS BY TIIE U. S. FISH COMMISSION STEAMER ALBATROSS. 

[Published by permission of Mon. Marshall Mcl)onsld, Commissioner of Fisheries.]
No. NXIN.-A REVISION OF THE ORDER HETEROMI, DEEP-SEA FISHES, WITH A DESCRIPTION OF THE NEW GENERIC TYPES MACDONALDIA AND LIPOGENYS.

By G. Brown Goode and Tarleton II. Bean.

The colleetion of heteromons fishes obtained by the U.S. Fish Commission includes representatives of three of the five known genera of the order. The first species was taken in 1880 by a New England fishing vessel from the stomach of a ground shark on the Gramil Bank of Newfomdland. The Albatioss secured its first specimen (a Mactonaldia) in 1884 off the coast of New Jersey, and again, in 1857, Aredged a second specimen of the same species n nearly the same locality.

In 1856 this vessel collected several examples of Notaconthus ctnatis. west of the Bermmdas, and in 1857 Lipogenys was dredged oft the Maryland coast.

Heteromi have been recorded from the Aretic, the Mediterranean, north and south Atlantic, and north and sonth I'acific, in depths ranging from 100 to upward of 1,500 fathoms.

## Orter HETEROMI.

Notacanthi, BleEker, Tentamen, 1859, xxili. (In part.)
Hetcromi, Gill, American Naturalist, November, 1889, p. 1016.
Teleosts with the seapular areh formed by the proseapula and post temporal (or posterotemporal), the latter detached from the sides of the cranium, and impinging on the supraccipital; the hypercotaroid and hypocoracoid coalesced into a single lamellar imperforate plate; the actinosts normal; the cranium with the condyle confined to the basioccipital (ill defined); the exoccipitals coalesced with the epiotics and opisthoties; the vomerobsolete; the opercular apparatus complete, but the preopereulum slightly comected with or discrete from the sus. pensorimm; the suborbitals suppressed; the jaw bones complete and little aberrant; the palatines, entopterygoids, and ectoptyergoids well developed; the anterior vertebre separate, and the ventrals abdominal (Gill.)

All the heteromons teleosts haveasubfnsiform, moderately compressed body, with head and snont protroding, and sometimes prodnced and proboseis-like as in Polyacunthonotus.

## Family Notacantildide.

Notacantini, Rafinesque, Indice d'Ittiologia Siciliana, 1810, p. 34.
Notacanthimi, Bonapamte, Cat. Metorlien, 1816, p. 72.
Notacanthoidei, Bleeker, l. ©.
Notacanthi, Giexther, Cat. Fish. Brit. Mns., in, 1861, p. 54.
Notucanthider, G11., Arr. F'am Fish., 1872, p. 21; Johnson's Cyelop:edia, m, 1883, Century Dictionary, iv, 402?.-Jomdan aml (filbeht, Bull., IT. S. Nat. Mus., xvi, p. 370.
Heteromous teleosts, with clongate, subfusiform, moderately compressed body. Head short and snont protrnding, sometimes produced, proboscis-like (as in Polyacauthonotus). Mouth moderate, horizontal, or inferior, suctorial (as in Macdonaldia). Scales small on body and head; lateral line present. Jeeth slender, closely set, in a single series in each jaw. Gill-openings wide, the membranes separate and free from the isthmus.

Dorsal fin median, with short and free dorsal spines, and with soft rays very few or absent. Anal fin long, rather high, extending from the middle of the body to the caudal, with which it unites, and with numerous spinousrays. Ventralsabdominal, often coufluent, with 1-5 spines and $4-8$ soft rays. Pectorals short and high. Psendobranchir, none.

The elaborate anatomical description of Notucanthus sexspinis given by Giinther* with nmmerons excellent figures, applies in its general featmes to all the members of this family.

In the discmssion of the genera and species below, little attention has been given to the degree of comection of the ventral fins. In every instance these are comate or conflnent, but the degree of comection depends not so murlh mpon their proximity to each other as upon the extent of the connecting membrane in the several forms, and we question whether the character ean be so defined as to serve even for specific llistinctions.

All the species examined by us have the peenliar modification of the posterior extremities of the maxillary, and the sharp spine more or less hidden by the fleshy fold of the lips at the angle of the month on either side.

KEY TU THE GENERA OF NOTACANTHID.E AN゙D LIPOGENYHDA.

Campylodon fabricii, Reinhalidt, Vidensk. Selsk. Afhandl., 1838, p. 120.
Notacanthns chemnitzii, Biocif, (Abh. Bolnm. Gesellsch., 1787).-JohDAN and Gilbert, liull. IT. S. Nat. Mus., xvi, p. 370.
A Notocanthas with elongate body, whose greatest height lies between the pectoral and ventral fins and is rontained about four and one-half times in the distance from the vent to the tip of the snont. Head short, compressed, its length not quite three and one-half times in the distance from vent to suont. Month large, extending backward to a point nearly moder the eye; the maxillary nearly to the vertical from the anterior margin of the pupil. The mouth does not lie entirely on the unter portion of the head, but is sublateral. There are thirty-five teeth in the intermaxillaries on each side. The distance between the upper protile of the head and the eye is about equal to the diameter of the eye, which is slightly greater than one-third the length of the snont (certainly not more than one-half the length of the snout) and about one-eighth the length of the head. [In this connection it is taken for granted that the hole in the skin of the head represents the size of the eye. If, howerer, we assume that the entire portion free of scales is the eye, the diameter is greater and ennal to one-sixth the length of the head. It is, at any rate, considerably less than the width of the interorbital space.] The gill-cover appears to be divided to below the symphysis of the opereulnm (with hyomandibular), and is free from the isthmus.

Scales are lacking only about the mouth and eyes; about forty rows of small scales ( 2 mm . broad, 4 mm . long) between the ventral ontline and the lateral line; smooth and imbricated.

Of the eleven dorsal spines, the first (overlooked by Bloch and Valenciennes) is very small and only visible as a point; placed close to this ( 1 mm .) is the second, which is also very short and feeble. The third, though also short, is thicker. The vent lies behind the fifth spine. Of the fifteen anal spines, which have their origin inmediately behind the vent, the first (overlooked by Bloch and Valeneiennes) is very small; it does not extend beyond the profile; the second and third but slightly. The spines which are longest and placed farthest back still bear traces of a comecting membrane, and are probably only wormoff rays. The pectorals are inserted somewhat farther back from the gill-covers than shown by Bloch; the end is smrely broken off, but yet it can hardly be doubted that this fin is too long in Bloch's figure; its base is less than one-sixth the length of the heal. The ventral fins, comected together behind the median line ly a membrane, terminate considerably in advance of the vent (they are apparently worn off a little behind).

Radial formula: D. 11; A. $1 \pi+118$. (? ; P. 1? ; V. $3+7(1), 8(\mathrm{r})$; Branchiostegals vim. (r)—iN. (l).

Totallength (restored). 85 ('m. Lengthof head, about 10.7 cm. Height of borly, about $S \mathrm{~cm}$. Length of candal, about 47.5 cm .

The full diagnosis given above was furnished by our friend Dr. Franz Hildgendorf, custos of the zoological eollections in the Royal Mnsemm of Natural History, Berlin, who also gives the following notes on the present condition of the type:

The original Bloch speeimen (Cat. gen. No. 1409) is still in existence (our museum possesses in addition to this only a single specimen of Notacanthus, Notac. sexspinis), but it is in a very unsatisfactory condition. It was perhaps injured in transportation from Paris. The jar has not been opened for more than thirty years. Very likely Bloeh received it in a poor state of preservation-a large cavity in the belly between the pectorals and ventrals, a dilapidated left eheek, injured eyeballs, intestines wanting. ete. In addition to this, there are other defects of a later date, such as the loss of the candal, the tip of the snont, the maceration of the frontal bones. The gill areh is almost entirely gone; the intestines altogether. The frontal hone is ernshed and the first vertebra is diseonnected. There is a long gap in the dorsal fin.

The actual length is now 82 em.; in addition to this should be added at the most 1 cm . for the snont and $\frac{2}{3} \mathrm{em}$. for the candal fin. This makes its former length about 85 em . (Bloch says $2 \frac{1}{2}$ feet. This would be aecording to the lhenish, i. e., Prussian, measure ouly $78 \frac{1}{2} \mathrm{em}$. Perhaps Bloch had a longer foot, or he gave only an approximate measurement.) As we have no other speeimen whieh we might have coufounded with that of Bloch, and ours still bears the label (apparently in Trosehel's handwriting), "Notucauthus uasns, Ieeland, Bloch," I have no donbt that No. 1409 is the type specimen. Nor can there have been another in Paris.

How much of the cud of the eandal is missing is difficult to say. The point of the fracture is hard and the tin bones are soft. If Valenciemes's aecount is aecurate, the candal fin only is missing, and one or two rays of this are still attached. If Bloch's description is correet, there were $149-(13,8$, or 10 ? spines for the candal $),=126-128$ rays in the anal; consequently a eandal end, with at least 10 rays, in addition to the eandal fin, was lost, and the fish would have been somewhat louger than 85 cm . I presume there was an oversight on Bloch's part.

The material now classed by anthors under the name of $N$. nasus is the following: (1) A specimen described by Fabricins in 1798 under the generie name of Campylodon, obtained in 1794 from Greenland; (2) Bloch's type in the Berlin Museum, believed by him to eome from the West Indies, described under the names N. chemnitzii (?), N. nasus, and Acanthonotus nasus; (3) a specimen, obtained off Iceland by La Recherche and brought by Gamard to the Paris Museum, figured in the Règne Animal, and said to have been figured also in the Voyage in Scandinavia; this, as has already been stated, is possibly a typical N. nasus; (4) a specimen, 3 feet long, obtained in Sontlı Greenland, and brought in 1877 to the Copenhagen Museum. This also is possibly not a characteristic representative of the species.

Both Canestrini and Giglioli enumerate Notacanthus nasus among Mediterranean fishes, but entirely without warrant.

## NOTACANTHUS ANALIS; (iill.

Notucauthus analis. Gille, Proe. U. S. Nat. Mus., VI, 1838, p. 255.-Cüxther, Chatlenger Report, xxif, p. 248, note.-Vanlant, Voy., Travailleur and Talisman, p. 318, ct seq.-Jordan and Gilibert, Cat. Fish. N. Amer., 1885, p. 58.

A Notacanthus, with its body much higher over ventrals than over pectorals, and comparatively short. Its height equal to one-third of the distance from the rent to the tip of the suout, and nearly equal to
the length of the head. The lateral line arenate in fiont of the dorsal spines, following profile of the back, and then sinking to the median line of the borly. Finst dorsal spine in front of vertical from insertion of ventral.

The snont is compresserl, pointed, much produced beyoud the moderate month. The cleft extemls nearly to the vertical through the middle of eye. The length of the snont is one and one-half times the diameter of the eye. The width of the interorbital area is slightly less than the diameter of the eye. The projection of the snont beyond the month equal to the diameter of the eye, or nearly so. The snout is compresised, not swollen. Month narrow, transverse, its width about one-fourth the length of the hearl. The eye is paced some distance below the upper protileand in the line of the lateral line continned to the nostrils. Gillopening wide; the membranes confluent and slightly in advance of the vertical from the upper end of the gill-opening; not attached to the isthmus. Scales very minnte, imbricated, adherent.

All the dorsal spines are short, the anterior very short; the second and first nearly over the origin of the ventrals, the fifth above the vent, and the sixth slightly behind the origin of the anal. The longest about one-half as long as the eye. The last (eleventh), which is followed by a single ray attached to it by membrane, is over the fifteenth spine of the anal. The dorsal spines are distant from each other, and behind each is a narrow angular membrane. The anal begins immediately behind the vent and in its middle portion is considerably elevated; the length of its longest rays are about equal to that of the snont, from which point it slopes rapidly to the tip of the tail. The pectoral, placed high up in the middle axis of the body, is inserterl at some distance behind the gill-opening and is broad and nearly oval in shape. Ventrals confluent, some distance in advance of the vent, stont, broad, ovate in form, not extending to the vent but separated from it by a distance equal to half their own length. Color miform light brown.

Radial formula: D. xi ; A. xvint.
This description is prepared from the types of Gill, (No. 378.56 , U.S. N.M.) from Albatross station 2677 , N. Lat. $32039^{\prime} \mathrm{W} . \operatorname{Lon} ., 76^{\circ} 50^{\prime} 30^{\prime \prime}$, in 478 fathoms. The types, two in umber, measure $11 \frac{1}{2}$ and $12 \frac{1}{2}$ inches, respectively. Another specimen (No. 44246 , U.S.N.M.) was obtained by the Albutross from station 2676 , in $32^{\circ} 39^{\prime} \mathrm{N}$. Lat., $70^{\circ} 01^{\prime} \mathrm{W}$. Lon., at a depth of 407 fathoms.

## NOTACANTHUS BONAPARTII, Risso.

Notarmuthus bonaparti, Risso, Wiegm. Arehiv f. Naturgesch., 1840, p. 37ti, pl. x.
Notuctuthes bomapartii, Filipri and Verany, Mem. Ace. Sei. Torino, xvir, 1857, 1. 190, Notad 6.-Canestrini, Pesei d'Italia, p. 118.-Moreav, Mist. Nat. Poiss. Franer, 1881, p. 161.—Gicilioli, Elenco, 33.
Notactuthus metiterraneus, Filipri and Veliany, Mem. Acc. Sci. Torino, 2 l series, Xソim, 1859, 1. 1910 (nota supra) ; Memi I'csci del Mediterraneo, 1857, 1. 3.Gíntuer, ('at. Fish. Brit. Mas., IIf, p. 5 . Canestrinı, Pescid Italia, 1872, p. 118.--Moneay, Hist. Nat. Poiss. France, 18st, 11, p. 158 (wooilent).-Vallmant, Voy. Thavallemr and Talisman, p. 317 ; p. 325 , pl. xxvin.

A Notucanthus, with body slender, comparatively elongate, little higher over ventrals than over pectorals; witl its lateral line inconspicnons, nearer to the dorsal than to the ventral ontline, not arched anteriorly. Snont produced and compressed. Palatine tecth in a single series. Ventrals joined by a membrane of considerable width between the internal rays. The height of the body is about one-thirteenth of its length; its thickness, about one-twentieth. The tail does not appear to be in the least truncated, though so deseribed by certain authors, oue of whom in his figure shows a tail carried to an acute point, making the length of the borly considerably greater in proportion to its height than is indicated in his own descriptiom. Color yellowish, with silvery reflections; the limb of the operculum, the margin of the orbit, and the month darker.
Radial formula: D. vi-vir; A. xir-100+; v. it, int-6 (IV-8 aceording to Filippi and Verany).

This form was carefnlly figured and deseribed by Risso in 1840. He had a single specimen 148 millimeters long, which he recognized as an inhabitant of abyssal repths (Nejeur alymes marines vasenx). By some error his description and figure, otherwise perfectly consistent, disagreed in respect to the number of spines in the dorsal fin, the figure showing 7, the description 9. Misled by this, Filippi and Veramy redescribed the same fish in 1859, and to justify their course proposed the theory that Risso's descriptions and figures were based on different specimens-a theory aecepterl without eriticism by later writers, but which we ean not believe a true one.

Risso was a carefuland experienced worker, and it would be unjust to the memory of one of the best Italian ichthyologists to almit that he could be guilty of such an error. Then, too, he states positively that he hat only a single specimen. It is much more probable that the German typesetter in the office of Wiegmamn's Archiv mistook a " $\tau$ " for a " 9 " in Risso's manuscript.

Risso's figure is a good one of a young N. mediterraneus and his description agrees with it perfectly with the exception of this one figure in type.

The specimen described and figured by Giinther under the name $N$. mediterreneus is not a Mediterrancan form, but one from the Southern Pacific, and has been referred by us to a new genns and species.

Morean is in error in referring the figures of Bloch and Cuvier and Valenciennes to this species. (See discussion under Notactuthus nasus.)
N. bonapartii was described muler the name $N$. mediterraneus by Filippi and Verany in 1857 from a speeimen obtained at Nice, and preserved in the Zoological Maseum at Turin. Two others from the same locality, referred by Morean to this species, are in the musenm in Paris. The Trarailleur and Talisman obtained four alditional individuals, one from the coast of Soudan, at a depth of 1,232 meters, and another
from the same region at 932 meters; two from the Banc D'Arguin at 1,49.5 meters. These last have been made the subject of an elaborate description by Vaillant, who also publishes a good figure.

This species is distinguished from N. sexspinis, (fig. 192A-B), described by Richardson from Anstralian Seas* and subsequently deseribed by Giinther, who also gives an excellent figure $\dagger$ by the various characters, most striking of which is the difference in the relationships of the position of the dorsal spines and the soft anal fin. In N. sexspinis the dorsal and soft anal do not pass the same vertical, whereas in $N$. mediterraneus the last three dorsal spines are placed over the anterior part of the soft anal. The National Musemu is indebted to Dr. Giinther for a specimen of Notucanthus sexspinus from New Zealand (No. 12625 , U.S.N.M.). It is a small specimen, and does not exhibit any inflation of the cheeks, snch as is shown in the plate in the Challenger report. It has eight dorsal spines.

The type of N. mediterrancus fiom Nice was examined by Giglioli at the Turin Museum in 1882. Its total length is 203 mm ., and its radial formula D. $6 / 1$; A. 12 / 132? ; V. 3-4 / 8; C.5?

Prof. Giglioli informs us that iu his "Central Collection of lataian Vertebrates" at Florence he has four specimens of N. bonapartii, as follows:
a. Nice, August 11, 1882. Total length, 153 mm. D. $8 / 1$; A. 6-7 / 120; V. 3/6-7; P. 9-10; C. 3-4 ?. A large curved spine in upper corver of mouth on either side.
b. Nice, March 7, 1891. Total length, 205 mum. 1). 7 / 1; A. 14 / 120; V. 3 / 7. P. 12. C. 4?. Buccal spines hidden in skiu.
c. Nice, June 15, 1892. Total length, 203 mm . D. 7 / 1. A. 8 ? / 140. V. 3 /5-7. P. $10 / 12$. Buccal spines large and prominent.
d. Syracuse, 1855-60?. D. 7 / 1. A. 11 / 25. P.9-10. V. 3 / 5. Tail broken off. Buccal spines conspicuons.
Another specimen, collected by Bellotti at Messina, December 12, 1882, and now in the Museo Civico at Milan, was examined by Giglioli, who states that it was 104 mm . long, and had D. $7 / 1$. A. $7 /$ ?. V. $3 / 6$. P. 10-12. C. 5 ?.

## NOTACANTHUS PHASGANORUS, Goode.

Notacanthus phasganor'us, Goode, Proc. U. S. Nat. Mus., In1, p. 535, Apr. 18, 1881.Günther, Challenger Report, xxir, p. 249.-Johdan and Gilbert, Bull. U. S. Nat. Mus., x yi, p. 900.-Vallant, Voy. Travailleur and Talisman, p. 318 et seq.
A Notacanthus, with its body a little higher over the ventrals than over pectorals, and comparatively elongate; with its lateral line slightly arched above the pectorals, sinking to median line of body in advance of first dorsal spines, and its last dorsal spine over the fifth from the last anal spine.

[^1]Its body is much compressed, its greatest width slightly more than one-third height of the borly at rent.

Scales romed, thin, Hexible, very small npon the head (not wider than the diameter of one of the domsal spines), but upon the anterior half of the body about three times as large, decreasing in size upon posterior half, until upon tal they are smaller than upon head. Number of scales in lateral line not fir from 400 . (ln the partially digester specimen before me it is mpossible to make an exact emmeration.) Number between lateral line and dorsal fin, abont 20 ; between lateral line and anal fin, about 36 . Head covered in every part, even the lips, with small scales, of which there are about 40 between eye and end of opercular flap. Scales deeply embedded (in life are probably hidden beneath a slimy eprdermis).

Length of the head abont $7 \frac{1}{3}$ in that of body. Bones are all Hexible, and their outlines are invisible without dissection, the whole being covered with a leathery skin. Width of interorbital space appears to be (in the motilated head) somewhat greater than length of snout and about one-fourth length of the head. Diameter of orbit appears to be about one-half width of interorbital space. Length of postorbital portion of head nearly three times that of snont. Length of mandibular bone slightly excecds twice diameter of eye; that of upper jaw considerably greater. Teeth in upper jaw blunt, acienlar, set side by side like the teeth of a comb, about 32 on each side. In lower jaw shorter, slenderer, and in double rows. Villiform teeth upon palatines.

Dorsal fin begins at a distance from suout not far from two and three-fourth times length of the head, and nearly over the one liundred and tenth scale of lateral line; it consists of ten low, widely separated spines, meonnected by any membrane. Distance between first and tenth spine nearly donble length of head.

Spines from fourth to uinth about equidistant, while the other interspaces are shorter.

Distance from snont to anal fin equal to about four times length of head. Anterior spinous portion of anal resembles dorsal and is devoid of connecting membrane. (The membrane is also absent from the posterior half of the fin, but may possibly have been destroyed.) Anal rays extend to tip of tail and number about 130 , the number of spines being 19. Anal begins immediately behind vent, and its length of base is slightly less than half that of body (less by a length about equal to the distance from the angle of the mouth to the gill-opening).

Pectoral fin placed at a distance behind the gill-opening about equal to width of its own base (its length is at least double this distancehow much more can not be determined, but the fin is evidently short and rounded in contonr, the upper rays longest). Its base is stout-peduncular, and thickly covered with seales.

Distance of the ventrals from snont equal to that of the dorsal,
though its insertion is slightly in advance of that of dorsal. Ventrals closely arlawent, separated by narow groove, broarl, with pedunclelike bases, thickly covered with scales, and are provided with two spines and dight or nine (as nearly as the specimen will permit determination) rays.
Padial firmula: I). x; A. xix (130); C. 0; P. (17); V. 11, 8-9.
The U. S. Fish Commission received the type from the schooner Gatherer, of (iloucester (Capt. Briggs Gilpatrick), whieh had been taken from the stomach of a (iromul-shark (Somuinsus brevipinnis), on the Grand Pank of Newfoundland.
(if GLIOLIA, new genms.
A gemus of Notacanthide, distinguished from Notacmenthes by the less advanced position of the dorsal, the first dorsal spine being placed in the vertical over the vent and close to the vertical from the first anal spine. Dorsal spines $6-9$; anal spines $15-18$, these being longerand more slender than in Notacanthus, enveloped nearly to their tips in a membrane, and grading impereeptibly in length and size into those of the anal, which is comparatively high. The greatest height of the body is in the region of the ventral fins, and the lateral line, which is conspicnous, is areled over the pectorals and ventrals, but follows closely the dorsal outline mutil it passes beyond the dorsal spines, after which it is directed in as straight line to the tip of the pointed tail. Head comparatively broad, month inferior, almost suctorial; teeth in each intermaxillary $20-22$; snout thick, swollen, much produced, nostrils large, conspienons, covered by a membranons flap. Peetoral short, broad, rounded. Ventrals plared low down and completely mited, extending to the rent.

In general appearance and proportions this form resembles the highbacked division of the genus Notacanthus, to which belong N. nasus and N. chemnitzii. Its month, however, is placed more on the under surface of the head than even in $N$. sexspinis, and resembles in some respects that of our new gemus. Macelonaldia.

This gemus is named in honor of Commendatore Enrico Hillier Giglioli, professor in the University of Florence and fomder of the Central MInsem of I talian Vertebrates, who has been identified with all the efforts of the Italian Govermment in deep-sea research, and whose thorongh works upon the geographical distribution of Italian vertebrates, both terrestrial and aquatie, are of an importance which can not be overstated.

The only species assigned to this genus is that obtained by the Challenger off the sonthwest coast of Sonth America, and referred by Giinther to Notacanthus bonapartii. For this form, represented by a single individual $11 \frac{1}{2}$ inches long, from a depth of 400 fathoms at station 1310, we propose the specific name moselcyi, in memory of the lamented Henry

Nottidge Moseley，F．R．s．，naturalist of the Challenger，and later Linacre professor in the University of Oxford．

GIGLIOLIA MOSELEYI，new speeies．

Plate XVIII，fig． 1.
Notacanthus bomapartio，G0nther，Challenyer Report，xxir，243，pl．lxi，fig．e．
The following excellent description is by Dr．（iiinther：
Body moderately elongate，its greatest depth opposite to the ventral fin，amd con－ tained $t$ wice and two－thirds in distance of the vent from the end of the snont；the length of the compressed oblong head is contained twice and one－third in the same length．The snout is thick，swollen，much prodnced berond the narrow transverse month，which is opposite to the front margin of the orbit，and quite at the lower siderof the head．Twenty teeth on each side of the mper jaw．The eye is close to the mper profile，two－thirls of the length of the snont，one－fifth of that of the head， and，less than the width of tho interorbital space．Gill openings of moderate width， the gill membranes being conflnent in the vertical from the upper end of the gill opening，and not attached to the isthmus．
＇The whole body and head are covered with minute，smooth，imbricate，and adher－ ent scales．

All the dorsal spines are short，the anterior very short，the seeond opposite to the vent．The anal spines commence immediately behind the vent and increase in length posteriorly，passing into the flexible rays，which are of varying and indefinite number．The pectoral is inserted at the usual distance from the gill opening and has a base of moderate width．Ventrals uniterl and extending to the vent（（iiinther）．

Radinl formula：D．VIlI－IX ；A．XV－XVIII，I50；C．3；P．9；V．I，7；Ciec．pyl． 5.

Travailleur and T'alisman, 335. pl. xxvii, tig 1.
[Sotucathus (Polyacanthonotus) rissoanus, Givemer Challenger Report, xxir, 1. 250 (description and figure relate to another species).]

Paradorichthys garibehdiamus, Giglioli, Nature, xxv, 1r. 535.
A Notacanthid fish, sleuder and elongate in form, its greatest height above the ams and near the mildle of the borly, one-fifteenth of the length of the body; its lieight at the shoulders about onetwentieth. The length of the head is abont one-eighth of that of the body. Snont very elongate, one-third of the length of the head; as long as the height of the body at the shoulders and three times the diameter of the eye. In form resembling that of Mhastucembelus. "The condition of the type," remarks Vaillant, "does not allow us to estimate the size of the month, but its comature does not reach the anterior adge of the mbit. Its form is analogons to that in other species of the gems, that is to say, its inferior teeth are exceedingly fine and closely set in the jaws, while there are stronger teeth upon the palate, where they are antanged in the form of a horseshe."

Eye moderate in size, its diameter one-eighth the length of the head; interombital space very narow, not one-half the diameter of the eye. hranchial opening large. Operculum trunated posterionly.

Vent in front of the middle of the borly.
No traces of scales. The lateral line, however, is conspicuons, and it descends from the upper angle of the operentan to the middle of the bonly, or a little below it, in the vicinity of the region of the vent. The first dorsal spine is placed two-thirds times its own length back of the vertieal from the axil of the pectoral, and its length is less than the diameter of the eye. The highest dorsal spines, those in the posterior thith of the fin, are twice as long as the diameter of the eye. The spines are all slightly curved backwarl, and there is a soft, supplementary ray behind the last. The anal spines are longer than the dorsal spines, the longest two and one-half times the diameter of the ege. The tirst, which is somewhat longer than the first dorsal spine, situated immediately behind the rent under the eighteenth dorsal spine.

In the specimen figured and described by Vaillant there is a semblance of a mimete, separate candal fin, but it is by no means certain that this exists. The pectoral is placed a considerable distance from the operculum, nearly equal to the length of the snont, and its lower axil is in the median line of the body, or nearly so. 1ts length is about equal to that of the suout. The ventrals, situated at a distance
from the snout equal to abont one-third of the length of the body, do not reach the anus, and are the same size as the pectorals. In Vaillant's specimen they appear to be separate, and he was able to observe but a single spine. The color, in fresh contition, was milky white; the head and iris being black.

Radial formula: D. 29-37; A. 34-41.
This species was known to Risso, who had in his collection the specimen which afterwards served De Filippi as a type and which is now in the Turin Musenm. A sketch by Risso of this fish, to which he never gave a name, is given in "Oceanic Ichthyology." The Turin specimen was examined by Prof. Giglioli in 185\% ; it is 160 mm . long and has the following radial formula: D. 29/1; A. 35.

Prof. Giglioli has three specimens in his collection at Florence. We are indebted to him for the following details concerning them:
a. Niee, August5, 1881 (type of Paradoxichthys ciaribaldiauns): Total length, 199 mm . D. $32 / 0$; A. $38 / 100$; P. $9-10 ;$ V. 1-10; C. 1 ?. This specimen has a loug, straight spine, pointed lackwarts, above the maxillary bone on either side.
b. Nice, March 1, 1891: Total length, i86 mm; 1). 30/1; A. 11/150; P. 10; V. 1/10; C. 4?. Found dead and partly decomposed. The peculiar maxillary spife is small in this and in the following specimen.
c. Nice, January 27, 1892: Total lemgth, 160 mm . 1). $30 / 0$; A. $34 /$; ? Fomel partially digested in the stomaeh of cialeus canis.
In addition to these specimens one other was taken by the French expedition off the const of Morocro, station 40, at a depth of 2,212 meters. Its radial formmla was 1 . $37 / 1 ; ~ \lambda .27 /$ ?.

MA(DONALDI A, new gems.
Notacanthids, with elongate body and inferior month. Body and head covered with minnte, imbricated scales. Dorsal tin represented by mmerons short, straight, robust, and disjoined spines, 27 to 34 in mumber, the first in advance of the insertion of the pectoral. Anal as in Notaconthus but lower, and with a longer portion of low, short, slightly curved, disjoined spines, from 35 to 55 in mmber, which under the final dorsal spines pass into flexible rays. Lateral line straight, conspicuons. Pectorals moderate, placed far back, below the middle line of the body and remote from the lateral tine. Teeth in jaws erect, small; and also in series on the vomer and palate. A line of pores on the immer edge of the mandible. Ventrals moderate, entirely separate. Type, Notucunthus rostratus, Collett.

This genus is mamed in honor of Col. Marshall Mebonahl, U. S. Commissioner of Fisheries, in commemoration of his liberal policy in furthering ichthyological research.

MACDONALDIA ROSTRATA (Collett) Goode and Bean.
l'late XVIII, fig. 2.
Notacanthus rostratus, Collet, Bull. Soe. Zool. Franee, 1889, p. 307.
The body is greatly compressed, its ontlines tapering rapidly in both directions from the origile of the vent. Its greatest height is con-
tained $3 \frac{1}{2}$ times in the distance of the vent from the tip of the snont, or abont four-fifths the length of the head, which is contained 9. ${ }^{2}$ times in the total. The snout is compressed, pointed, snake-like, prodnced beyond the month a distance less than the diameter of the eye, and contained three times in the length of the head. The month is small; its cleft scarcely reaches to the anterior nostril. Each jaw is armed with a series of minute teet hand a similar series on vomer and palate. The eye is morlerate in size, placed not far from the dorsal profile, distant abont 21.2 diameters from the end of the snont, more than three times from the end of the opercle. Gill opening wide. The body ant head covered by minute, imbricated scales. A line of mucous pores extends from the anterior end of the lateral line forward moler the eye and thence to the end of the maxilla.

The dorsal spines are short, distant from one another, the first being over the end of the opercle, the fifth slightly behind the vertical through the origin of the pectoral, the twelfth slightly in advance of the origin of the pectoral, tice fifteenth ahmost over the origin of the anal, and the last (twenty-eighth) a little behind the middle of the length of the tail. In another individual the fourth spine is immediately over the pectoral insertion, the thirteenth over the ventral origin, and the whole number of spines is 30 , but there is behind the thirtieth a minnte spine almost mited by membrane. The anal begins immediately behind the vent, and after the fifth spine the height of the fin remains miform until the length of the rays gradually decreases near the tip of the tail. The pectoral is inserter at a distance from the gill opening nearly twice its own length. The ventrals have a broad base, are not confluent and reach to the vent or slightly beyond it.
D. NXTHI-XXXI; A. NLIL-LIII.

The types are No. 35601, U.S.N.M., and were obtained by the steamer Albatross at station $\because 216$, latitude $39 \circ 47^{\prime}$ N., longitude $70^{\circ} 30^{\prime}$ $30^{\prime \prime}$ W., in a depth of 963 fathoms. They measure 16.2 and 16 inches, respectively. Another specimen, 17 inches long, was obtained by the same stemmer at station 2553, latiturle $39^{\circ} 48^{\prime}$ N.. longitude $70^{\circ} 36^{\prime} \mathrm{W}$., $i_{11}$ a depth of 5.51 fathoms.

Closely allied to M. rostrutu is Notacanthus challengeri (Vaillant) (Notacanthus rissoanus, Giinther, Challenger Report, XXII, 250, pl. LXI, Fig. B: not Filipli and Verany), renamed by Vaillant in the report of the Travaillenr and Talisman, page 387 . 'This is distingnished by the larger mmber of its dorsal rays, the less anterior position of the origin of the donsal, the lesser height of the body in comparison with the distance from the vent to the snont, comparatively longer snout and larger eye, and the absence of the suborbital row of mucons pores.

Dr. Giinther states that althongh the species is a matter of some certainty, the diagnosis of $N$. rissoanus "applies sufficiently well to his specimen;" further remarking that "since a number of Merliteranean fishes are identical with Japanese, and at least one other species
of Notacanthus, N. bonaportii, shows a wide geographical range, he should not feel justified in giving a distinct name to the fish described." We can not help feeling that Dr. Giinther has departed from his enstomary cantious and scientific method in this case, and are satisfied that he would not have done so had he seen the specimen obtained by the French Exploring Expedition on the coast of Moroceo, and described and figured by Vaillant. Coming as it does from the Meditermanean region, and having a proboscis-like character of the snont, much more emphasized than in the Japanese form, the presmmptions in favor of its identity with $N$. rissoamus are very strong. We therefore not only adopt the identification of Vaillant, in preference to that of (xiinther, but accept the new name which Vaillant has proposed for the Japanese form.

Family LI'OGENYIDAE.
Lipoyenyide, Gill, MS.
Heteromes with aroundish, inferior, suctorial month; imperfect lower jaw with its rami separated at middle, comected with the corresponding sides of the upper jaw, and invested in a thick, transversely plicated horseshoe-shaped lip, reflected upward behind on the cheeks; no teeth; short row of four or five partially comected graduated dorsal spines, and five to seven branched rays, forming a regular fin. (Gill.)

The anomalons and mexampled monification of the lower jaw and month deserves a detailed anatomical examination; but the existence of only one specimen for the present, at least, is deemed to render such an investigation inadvisable.

## LIPOGENYS, new genms.

Head and body compressed, the body elongate as in Fotacanthus. Snont produced, compressed, obtuse at tip. Cleft of the month inferior, suctorial, circular in front, surounded by rusose, contractile lip, with cleft posteriorly flanked by wing-like flaps, containing the modified mandibulary bones which articulate with the end of the maxilla, and are free behind. A concealed spine at the end of the maxilla. No teeth. Anterior nostril in short tube, the posterior oblong, under a short flap. Dorsal fin short, but normal and well developed, with a distinct soft portion. Anal fin normal in position, high, with many spines, aud with some of the rays spine-like, thongh forked. A distinct though very small caudal fin. Ventrals normal, well developerl, with several spines. Scales minute, very numerous. Lateral line conspicuons.

LIPOGENYS GILLII, new speeies.
Plate XVIII, fig. 3.
Body compressed, its greatest width one-half its height, which is about one-tenth of the length. The length of the head is contaned $8 \frac{2}{3}$ times in that of the body and twice in the distance from the origin
of the pectoral to the vent. The wilth of the interorbital space is about equal to the diameter of the eye, which is one-fifth the length of the head. The length of the snout is abont one-fourth that of the head. The postorbital portion of the hear is twice as long as the snout. The peculiar form of the jaws and month has been described under the head of the genus. The diameter of the circular opening is about one half the diameter of the eye. The dorsal fin begins at a distance from the snont equal to about three times the length of the hearl. It consists of five graduated spines, of which the first is minute and the longest as long as the smout, and five rays, of which the second is lougest, nearly one-half as long as the head. The spines and rays are all compactly arranged in a strong triangular fin. The length of the dorsal base equals one-half that of the head. The anal begins under the fourth spine of the dorsal; it contains 41 spines and Ss rays, of which the anterior 10 are stiff, though articnlated, and divided at the tip. The longest ray is longer than the longest spine, abont as long as the snout. The ventral consists of seven spines and seven rays. The two fins almost meet in the median line, but are disconnected. The fin reaches to the vent. Its distance from the $\mathrm{tip}_{\mathrm{p}}$ of the suont is about $2 \frac{1}{2}$ times the length of the head. The pectoral is placed below the median line of the body, at a distance from the head abont equal to the diameter of the eye; its length is a little greater than the postorbital part of the head. The lateral line is well developed anteriorly, becoming obsolete at a distance from the end of the dorsal about equal to $2 \frac{1}{2}$ times the length of the head.

The color is uniform light brown. The under side of the gill covers dark, showing dark at the edges of the opercular bone.

The type measures 17 inches in length. It is No. 39212, U.S.N.M., and was taken by the steamer Albutross at station 2742 , in N. lat. $37^{\circ}$ $46^{\prime} 30^{\prime \prime}$; Wr. lon. $73^{\circ} .56^{\prime} 30^{\prime \prime}$, from a depth of 865 fathoms.
